Codebase Audit Report

TravelBooking-Korean (CheapestGo)

Branch: `new-update`

Generated: March 19, 2026

Framework: Next.js 16.1.2 · Supabase · LiteAPI · Stripe · Duffel/Mystifly

Scope: 9-phase comprehensive audit covering booking reliability, post-booking, monetization, admin, search, UX, security, testing, and growth.

Table of Contents

1. Phase 1 — Booking Reliability
2. Phase 2 — Post-Booking & Email
3. Phase 3 — Monetization & Revenue
4. Phase 4 — Admin Dashboard
5. Phase 5 — Search & Discovery
6. Phase 6 — UX & Frontend
7. Phase 7 — Security
8. Phase 8 — Testing
9. Phase 9 — Growth & Scalability
10. Appendix A — Fixes Applied (Phase 1 & 2)

Phase 1 — Booking Reliability

Hotel & flight booking confirmation flows, payment handling, state machines

CRITICAL `success: true` returned when DB save fails

`src/lib/server/bookings.ts:268–302`

`confirmAndSaveBooking()` calls LiteAPI to confirm the hotel booking, then attempts an atomic DB save via RPC. If the DB save fails (either `rpcError` or a thrown exception), the function returned `success: true` with an error message string. The API route treated this as a successful booking — never triggering a Stripe refund, creating a success notification, and returning a success response to the client.

Impact: The user sees "Booking Confirmed" but the booking never appears in `/trips` because it's not in the database. The hotel IS booked and payment IS charged, but there's no record in the system.

```
// BEFORE (bug):
return {
  success: true,  // ← WRONG: DB failed, but tells caller it succeeded
  data: { bookingId, status, ... },
  error: 'Booking confirmed but failed to save...',
};
```

FIXED Changed to `success: false` with `liteApiConfirmed: true` flag. Route now handles this case separately — does NOT refund Stripe (hotel is booked), creates CRITICAL admin notification for manual reconciliation.

CRITICAL No double-click prevention on hotel booking confirm

`src/lib/server/bookings.ts:150–180`

No concurrency guard existed on `confirmAndSaveBooking()`. If the user double-clicks the "Confirm" button, two parallel requests reach LiteAPI, potentially creating **two hotel bookings** for the same room. Unlike flights (which have idempotency keys and a state machine), hotels had zero protection.

Impact: Duplicate hotel bookings charged to the user's card. LiteAPI doesn't deduplicate by prebookId.

FIXED Added in-memory `Set<string>` guard keyed by `prebookId`. Second concurrent request for same prebookId is immediately rejected. Set is cleaned in `finally` block.

HIGH Route refunds Stripe even when hotel IS booked (after DB failure)

`src/app/api/booking/confirm/route.ts:55–68`

After fixing the `success: true` bug above, `confirmAndSaveBooking` now returns `success: false` for DB failures. But the route's existing logic would then fall through to the Stripe refund block — refunding the user even though the hotel booking IS confirmed in LiteAPI. This would mean: hotel booked, user refunded, company eats the cost.

FIXED Added `result.liteApiConfirmed` check before the Stripe refund block. DB-failure-after-LiteAPI returns HTTP 500 with booking data + error message. Stripe is NOT refunded. Admin is notified via `createNotification` with CRITICAL severity.

MEDIUM

No DB-level idempotency for hotel bookings

`src/lib/server/bookings.ts`

The `bookings` table does not store the `prebookId`, so there's no way to check if a booking for a given prebook was already created. Full idempotency would require adding a `prebook_id` column with a unique constraint — but this was out of scope (no DB migrations).

Status: Documented. The in-memory concurrency guard mitigates the primary risk (double-click). Server-restart race conditions remain a theoretical edge case.

MEDIUM

No state machine for hotel bookings

Unlike flight bookings (which have a state machine: `pending → booked → awaiting_ticket → ticketed`), hotel bookings have no formal state transitions. The `status` field is set ad-hoc (`'confirmed'`, `'cancelled'`, `'cancelled_refunded'`) without validation of allowed transitions.

Status: Documented. Implementing a state machine would require application code + potentially DB constraints. Low practical impact since hotel lifecycle is simpler than flights.

Phase 2 — Post-Booking & Email Reliability

Email notifications, webhook handlers, post-booking automation

CRITICAL

Hotel booking: NO confirmation email sent to guest

src/app/api/booking/confirm/route.ts

The `sendBookingConfirmationEmail()` function existed in `email.ts` with a full HTML template, but was **never called** from the confirm route. After a successful hotel booking, only an admin notification was created — the guest received nothing.

Impact: Hotel guests have no confirmation email with booking ID, property details, dates, or price.

FIXED Added `sendBookingConfirmationEmail()` call with booking details from `result.data` and `body` params. Fire-and-forget pattern (non-blocking).

CRITICAL

Hotel cancellation: NO email sent to guest

src/app/api/booking/cancel/route.ts

No cancellation email function existed for hotels. The cancel route only created an admin notification. Guests were not informed of cancellation status or refund details.

FIXED Created `sendHotelCancellationEmail()` with refund status (refundable/non-refundable), booking details, and refund amount. Wired into cancel route with DB lookup for property details.

HIGH

Hotel amendment: NO email sent to guest

src/app/api/booking/amend/route.ts

No amendment email existed. Guests were not notified when their booking details were updated.

FIXED Created `sendHotelAmendmentEmail()` showing updated fields. Wired into amend route.

HIGH Flight supplier webhook: NO email on ticket issued or refund confirmed

`src/app/api/webhooks/flight-supplier/route.ts`

When suppliers (Duffel/Mystifly) sent async events for ticket issuance (`order.tickets_generated`) or refund confirmation (`order.cancellation.confirmed`), the webhook updated DB status and created admin notifications, but **never emailed the passenger**.

FIXED Expanded DB select to include `passenger_email, passenger_name, segments, total_price, currency` . Added `sendFlightBookingConfirmationEmail()` on ticketed events and `sendFlightRefundEmail()` on refunded events.

MEDIUM `sendBookingConfirmationEmail` returns `success: true` when email not sent

`src/lib/server/email.ts:261`

When the Resend API key was not configured, or when Resend returned an error without throwing, the function fell through to `return { success: true }` . Callers couldn't distinguish between "email actually sent" vs "email silently queued/failed".

FIXED Now returns `{ success: false, error: 'RESEND_API_KEY not configured' }` or `{ success: false, error: 'Email sending failed' }` in those cases.

MEDIUM Fire-and-forget email pattern with no retry

All email calls use `.catch(e => console.error(...))` — errors are logged but never retried. The `email_logs` table records failures, and the admin dashboard has a manual retry button, but there's no automatic retry pipeline.

Status: Documented. Automatic retry would require a background job/queue system (e.g., pg_cron + Edge Function). Manual retry is available via admin dashboard.

MEDIUM

Dual email logging tables

Hotel emails log to `booking_emails` table. Flight emails log to `email_logs` table. Different schemas, different admin queries needed. Creates blind spots in email monitoring.

Status: Documented. Consolidation would require a DB migration (out of scope).

MEDIUM

Cron jobs exist but are not scheduled

`supabase/functions/poll-pending-tickets/index.ts`
`supabase/functions/flight-reconciliation-job/index.ts`

Two Supabase Edge Functions exist for ticket polling and flight reconciliation, but the `pg_cron` scheduling setup is only documented in code comments — never actually configured. Without these cron jobs, `awaiting_ticket` bookings can expire without auto-refund.

Status: Documented. Requires Supabase SQL editor access to configure `pg_cron` (infrastructure, not code).

Email Coverage Summary (After Fixes)

Event	Hotel	Flight
Booking Confirmed	NOW SENT	✅ Sent (async)
Ticket Issued	N/A	NOW SENT
Refund Processed	NOW SENT	NOW SENT
Cancellation	NOW SENT	✅ Sent (async)
Amendment	NOW SENT	N/A
Awaiting Ticket	N/A	✅ Sent (async)

Phase 3 — Monetization & Revenue

Stripe integration, vouchers, pricing, revenue tracking

MEDIUM

Voucher validation lacks rate limiting

src/lib/server/vouchers.ts

The `validateVoucherServer()` function validates voucher codes against the DB but has no rate limiting. An attacker could brute-force voucher codes by trying thousands of combinations. Server Actions provide CSRF protection but not rate limiting.

MEDIUM

Currency conversion uses static rates

src/lib/currency.ts

Currency conversion uses hardcoded exchange rates. No mechanism to update rates from an external API. Displayed prices may be inaccurate if rates drift significantly.

LOW

No revenue analytics aggregation

The `booking_financial_events` ledger tracks individual transactions but there's no aggregation layer for total revenue, average booking value, or conversion funnels. The admin dashboard shows raw booking counts but not financial KPIs.

Phase 4 — Admin Dashboard

Admin tools, monitoring, recovery, command palette

MEDIUM

Admin auth relies on hardcoded email check

src/lib/server/admin/

Admin routes check if the authenticated user's email matches an admin list (likely from env vars). No role-based access control (RBAC). If an admin email is compromised, all admin functions are accessible.

LOW

Recovery tools are manual-only

src/lib/server/admin/recovery.ts

Functions like `adminForceStatusRecheck()`, `adminRetryBooking()`, and `adminCancelAwaitingTicket()` exist but require manual admin intervention. The monitoring dashboard detects mismatches (payment without booking after 5 minutes) but doesn't auto-recover.

LOW

No audit log for admin actions

Admin operations (force cancel, force refund, restore booking) update the `cancellation_log` JSONB array but there's no centralized admin audit log table. Difficult to answer "who did what and when" across different admin actions.

Phase 5 — Search & Discovery

Hotel search, autocomplete, filters, property details

MEDIUM

Search results not cached

Every hotel search calls the LiteAPI Edge Function without caching. Identical searches within seconds hit the API again. React Query provides client-side caching but server-side has none.

LOW

Autocomplete debounce is client-only

`src/components/search/DestinationPicker.tsx`

Destination autocomplete debounces on the client side but the Edge Function has no rate limiting. Fast typing with poor network could result in multiple concurrent API calls.

LOW

No search analytics

Search queries are not logged. No way to understand what users search for, which searches return empty results, or popular destinations.

Phase 6 — UX & Frontend

Component architecture, accessibility, responsive design, performance

MEDIUM

No loading skeletons on search results

When search results are loading, the UI shows a basic spinner or empty state. No skeleton placeholders that match the card layout, causing layout shift when results appear.

MEDIUM

Checkout form has no field-level validation feedback

The checkout form validates on submit but doesn't show inline validation errors as the user types. Guest name, email, and payment fields could benefit from real-time validation using the existing Zod schemas.

LOW

Missing ARIA labels on interactive elements

Several interactive elements (TiltCard, HorizontalScroll arrows, tab lists) lack proper ARIA labels and roles. Screen readers may struggle with the landing page carousel and filter components.

LOW

Large Framer Motion bundle

Framer Motion is imported in many components. The full library adds ~30KB gzipped. Consider using `framer-motion/m` (tree-shakeable) or `motion` (lightweight subset) for simple animations.

Phase 7 — Security

Authentication, authorization, input validation, API security

HIGH

Flight supplier webhook has no signature verification

`src/app/api/webhooks/flight-supplier/route.ts:18–19`

The webhook handler has a comment: *"SECURITY: In production, verify supplier cryptographic signatures here"* — but no verification is implemented. An attacker who discovers the endpoint URL could send fake events to change booking statuses or trigger refunds.

```
// SECURITY: In production, verify supplier cryptographic signatures here
// (e.g. Duffel webhook secret, or Mystifly token)
// ← NOT IMPLEMENTED
```

MEDIUM

LiteAPI key properly secured in Edge Functions

The LiteAPI key is stored in Supabase Edge Function environment variables, not exposed to the client. This is correctly implemented. Server Actions and API routes call Edge Functions which add the API key server-side.

Status: ✅ Correctly implemented.

MEDIUM

Ownership verification on all booking mutations

`cancelBooking`, `amendBooking`, and `getBookingDetails` all call `verifyBookingOwnership()` before proceeding. This ensures users can only modify their own bookings.

Status: ✅ Correctly implemented.

LOW **No Content Security Policy headers**

The application doesn't set CSP headers. While Next.js provides some built-in XSS protection, explicit CSP headers would add defense-in-depth against script injection.

LOW **Email templates use `escapeHtml()` — properly sanitized**

All email templates pass user-provided data through `escapeHtml()` before interpolation. This prevents XSS in email clients.

Status: ✅ Correctly implemented.

Phase 8 — Testing

Unit tests, integration tests, E2E coverage

HIGH **No test suite detected**

No test files (`*.test.ts` , `*.spec.ts`) were found in the repository. No test runner configuration (Jest, Vitest, Playwright) was detected. Critical business logic (booking flows, cancellation calculations, policy normalization) has zero automated test coverage.

MEDIUM **Zod schemas provide runtime validation but no tests**

The application uses Zod schemas for input validation (`prebookSchema` , `bookingConfirmSchema` , etc.), which is good. But there are no tests verifying that these schemas correctly reject invalid inputs or accept valid edge cases.

Phase 9 — Growth & Scalability

Performance bottlenecks, scaling readiness, technical debt

MEDIUM

In-memory concurrency guard doesn't survive server restarts

The `inflight` Set used for hotel booking double-click prevention is in-memory. If the Next.js server restarts mid-request, the guard is lost. In a multi-instance deployment (e.g., Vercel), each instance has its own Set — so parallel requests to different instances could bypass the guard.

Mitigation: For production multi-instance deployments, consider Redis-based locking or a DB unique constraint on prebookId.

MEDIUM

No database connection pooling configuration

Each API route / Server Action creates a new Supabase client. While Supabase handles connection pooling on their end, the application doesn't configure pool sizes or connection timeouts for high-traffic scenarios.

LOW

No image optimization for property photos

Property and deal images use raw URLs from LiteAPI / static data. No `next/image` optimization (lazy loading, WebP conversion, responsive srcsets) is applied in cards.

LOW

Bundle size could be reduced

Full imports of `framer-motion`, `lucide-react`, and `@supabase/supabase-js` in client components. Tree-shaking helps but explicit selective imports would reduce initial bundle.

Appendix A — Fixes Applied

Phase 1 & Phase 2 bug fixes implemented in this audit

Files Modified

File	Changes
`src/lib/server/bookings.ts`	• Fixed `success: true` → `success: false` + `liteApiConfirmed` flag (2 locations) • Added in-memory concurrency guard (`inflight` Set) • Extracted inner function `_confirmAndSaveBookingInner()` • Added `totalPrice` and `currency` to `ConfirmAndSaveResult.data`
`src/app/api/booking/confirm/route.ts`	• Added `liteApiConfirmed` handler (no Stripe refund, CRITICAL admin notification) • Added `sendBookingConfirmationEmail()` call on success
`src/app/api/booking/cancel/route.ts`	• Added `sendHotelCancellationEmail()` call with booking details + refund info
`src/app/api/booking/amend/route.ts`	• Added `sendHotelAmendmentEmail()` call with changed fields summary
`src/lib/server/email.ts`	• Fixed deceptive `success: true` in `sendBookingConfirmationEmail` • New: `sendHotelCancellationEmail()` with HTML template + refund banner • New: `sendHotelAmendmentEmail()` with HTML template
`src/app/api/webhooks/flight-supplier/route.ts`	• Expanded DB select to include passenger email/details • Added `sendFlightBookingConfirmationEmail()` on ticketed events • Added `sendFlightRefundEmail()` on refunded events

`src/lib/server/index.ts`	• Added barrel exports for new email functions

Severity Summary

Severity	Total Found	Fixed	Documented
CRITICAL	4	4	0
HIGH	5	3	2
MEDIUM	14	2	12
LOW	8	0	8
Total	**31**	**9**	**22**

Build Verification

All changes pass `npx tsc --noEmit` with zero errors. No runtime tests available (Phase 8 finding).

Constraint applied: No database migrations, no deployments, no schema changes.
